

Q: What should I check when a Kubernetes pod keeps restarting?

A: Check the pod restart count, container logs, previous container logs, pod events, liveness and readiness probe failures, resource limits, and recent deployment changes.

Q: What is a liveness probe failure?

A: A liveness probe failure indicates that Kubernetes considers the application unhealthy. Kubernetes may restart the container when the liveness probe repeatedly fails.

Q: What is the difference between a readiness and liveness probe?

A: A readiness probe determines whether a pod should receive traffic. A liveness probe determines whether the container is healthy enough to continue running.

Q: How can I investigate a deployment problem?

A: Check deployment rollout status, replica availability, pod status, pod events, container logs, configuration changes, and resource constraints.

Q: What namespace contains the production workloads?

A: Production workloads are deployed in the production Kubernetes namespace.

Q: Which cluster hosts the PaymentService?

A: PaymentService runs on the production-cluster Kubernetes cluster.
