

Q: What should I check when PaymentService is unavailable?

A: First check the Kubernetes pod status and recent pod restarts. Verify that the PaymentService deployment is healthy and that at least one pod is ready. Then check application logs for database connection errors, transaction timeouts, or failed health probes.

Q: What should I check when PaymentService pods keep restarting?

A: Check the pod restart count, container logs, liveness probe failures, and recent deployment changes. If the logs show database transaction timeouts, investigate PostgreSQL connectivity, active transactions, and database resource utilization.

Q: How do I investigate a failed PaymentService deployment?

A: Check the deployment rollout status, pod events, container logs, configuration changes, and health probes. Verify that the deployment is using the expected application version and that the application can connect to its dependencies.

Q: What dependencies should be checked when PaymentService has errors?

A: PaymentService depends on Payment PostgreSQL, Production Redis, and NotificationService. Kubernetes cluster and deployment health should also be checked.
